Q: What is the difference between polymorphism and strategy design pattern? It seems that they are somehow similar, but in some way they are different. What is the difference between polymorphism and strategy design pattern? What is the difference between strategy pattern and active record pattern? A: A polymorphic object is a type with a list of (related) implementations, and an API that allows you to choose which implementation to use. For example, you might have a system that represents a "part", with a list of other "parts" that it can be joined to, such as a train or a ship, or whatever. You want to write a function to make a new ship object, but you don't want to just create a new class, because that would take away from the polymorphic nature of the problem. A strategy is a way to change the behaviour of an object in a specific way. For example, you might have a function that takes a Part object and creates a Ship object, but the Ship object is a "mini-shipping" concept, so it doesn't work with other kinds of parts. You need a specific function that changes this behaviour, so you make a Strategy class that has this function. Both of these are ways to address the general problem of describing how the object is to be used. In the case of strategies, the difference is that you can specify how to use the object at an API level, instead of having to create a new class to achieve this. In the case of polymorphism, you can use the exact same implementation to address different kinds of problems. Strategies are an abstract design pattern that is usually built around the polymorphic object. If you look at the strategy pattern in its standard presentation, this will usually be the case. A: Strategies are a well known way of implementing the strategy design pattern. Here is
